Comparisons

Conclusion

Simultaneous Game vs. Sequential Game

- Given n players in simultaneous game, each has action space A_i
- The sequential version: order the players from 1 to n
- Strategy is from $A_1 \times A_2 \times \dots \times A_{j-1}$ to A_j for player j
- SPNE(Subgame Perfect Nash Equilibrium):
In all subgames, the player in turn makes a no-regret choice

SPNE vs. NE

- Perfect information: players fully observe what the predecessors do
- If perfect information, SPNE exists and can be derived using backward-induction
- $NE \subset SPNE$, for the sequential game itself
- In general not a NE for the simultaneous game

Comparisons

Conclusion

Machine Cost Sharing: Model

- n jobs (players)
- m machines
- R_i : the set of machines that job i can choose
- $\gamma_r(x)$: **decreasing** cost function for machine r
- Machine $s_i \in R_i$ is chosen by job i (strategies)
- Cost function is given by:

$$c_i(S) = \gamma_{s_i}(n_{s_i}) \text{ where } n_r = |\{j \in N; s_j = r\}|$$
- Fair cost allocation: $\gamma_r(x) = c_r/x$

Simultaneous Version: PoA and PoS [2]

(a) $\text{PoA} = O(n)$

(b) $\text{PoS} = O(\log(n))$

Sequential Version: SPNE and SPoA [1]

(c) SPoA = 1

(d) SPoA = $O(\log(n))$

- $O(\log(n))$ -optimal SPNE
- Can be found by a simple $O(\log(n))$ greedy algorithm
- SPNE is independent of the order of the sequence
- $\Rightarrow SPNE \in NE$

Concept and Result

- Coordination reduces cost
- By choosing "coordination machines", former players can expect latter players to join (cannot be done in simultaneity)
- SPoA also improves (compared to PoA) in the following games:
 - Unrelated Machine Scheduling Games
 - Consensus Games
- In Cut Games(opposition of Consensus Games), SPoA is worse

Comparisons
Conclusion

Symmetric Atomic Network Routing: Model

- Directed graph $G(V, E)$
- Source and destination $s, t \in V$
- A **linear** latency function $l_e(x) = d_e(x)$ for each $e \in E$
- n players traveling from s to t (symmetric)
- Each player choosing one $s - t$ path (strategies)
- Cost function is given by: by choosing path A_i ,

$$c_i(A) = \sum_{e \in A_i} d_e n_e,$$
 where $n_e = \sum_{i=1}^n |A_i \cap \{e\}|$ is # of players using e .

Previous Work on This Model

- For atomic case:
 $PoA = 5/2$, tight for $n \geq 3$ (Christodoulou, 2005) [4]
- For non-atomic case: (comparison)
 $PoA = 4/3$ (Braess's Paradox!) (Roughgarden, 2001) [5]
- For sequential version of the game:
 $SPoA < PoA$ for small n (de Jong, 2014) [6]
- de Jong and Uetz thought that SPoA is also $5/2$.

SPoA of Two-player Games
SPoA of N-Player Games

Simultaneity vs. Sequentiality

Comparisons
Conclusion

Two-player Network Routing

- $PoA = 4/3$ (Why?)
- It is proved that $SPoA = 7/5$ in this paper
- Upper bound is proved by linear programming (omitted)
- Lower bound: an example

Lower Bound Example

FIGURE 2. Lower bound example for 2 players. Numbers are arc latencies.

SPoA of N-Player Games

Simultaneity vs. Sequentiality

Comparisons
Conclusion

SPoA of N-Player Game is Unbounded

FIGURE 4. A lower bound instance of a network routing game. Players travel from s to t .

There are $n = p\sqrt{x} + 5x^2$ players, while n is large enough (larger than disjoint strategies).

SPoA of N-Player Game is Unbounded

- Optimality: each player chooses 1 arc from each segment (Players share arcs as little as possible)
- Optimal social cost is $p\sqrt{x} + 7x^2$.
- An algorithmic SPNE is constructed
- Threaten former players and force inefficient strategies
- Threatening cost is low for latter players; high for former
- SPNE social cost is $p\sqrt{x}x + 7x^2$.
- $SPoA \rightarrow x$.

The Curse of Sequentiality [3]

Symmetric Atomic Network Routing Games
SPoA of Two-player Games
SPoA of N-Player Games

Simultaneity vs. Sequentiality

Comparisons
Conclusion

Comparisons

Game	PoA	SPoA	Winner
Machine Cost Sharing	$O(n)$	$O(\log(n))$	Sequentiality
Consensus Games	∞	1 (SPNE=opt)	Sequentiality
Cut Games	2	$2 \leq \text{SPoA} \leq 4$	Simultaneity
2-p Linear Routing	4/3	7/5	Simultaneity
General Linear Routing	5/2	∞	Simultaneity

Q: How to decide the winner?

Revisit NE vs. SPNE

- In NE, everyone decides simultaneously
→ some kind of fairness
- In SPNE, the order of players create unfairness
- An important concept of SPNE:
SPNE is supported by threats on off-equilibrium actions
- How about threats cannot be formed?

On Externality

- Ironically, in Machine Cost Sharing Games
latter players can do only **positive externalities** on formers
- $SPNE \subset NE$; in fact they are the best NE's
- While in Linear Routing Games
latter players can do only **negative externalities** on formers
- Exist some $SPNE \not\subset NE$; they are far more inefficient
- Threats are constructed on negative externalities

The Curse of Sequentiality [3]

Symmetric Atomic Network Routing Games
SPoA of Two-player Games
SPoA of N-Player Games

Simultaneity vs. Sequentiality

Comparisons
Conclusion

Conclusion

- Insight: from the nature of games, we may see whether simultaneity or sequentiality does better
- However, even in games with negative externalities, sequentiality may help avoid bad (unfortunate) NE.
Ex: Traffic lights, Consensus games
- My guess: SPoA(sequentiality) is better most of the time, but society needs not only efficiency but also fairness
